

WT CORRECTIONS APPLIED IN S2MA

Empty test section corrections

These corrections result from wind tunnel calibration. They consist of:

- a Mach number correction, corresponding to the Mach number deviation between the wind tunnel reference pressure taps and the abscissa of the reference point of the model measured during the test section calibration.
- a drag correction due to the buoyancy induced on the model by the static pressure gradient measured during the test section calibration.
- an incidence correction due to test section upwash, generally derived from lift measurements on the model in upright and inverted positions or possibly derived from clinometry measurements in the test section.

Wall and sting effects

These effects are induced by the presence of the test section wall and the sting line around the model.

- Analytical method:

Corrections in Mach, incidence, drag coefficient and moment coefficient are calculated by an analytical method (DXV877 software). A mathematical description of the flow around the model and its sting is obtained by means of some hundred singularities (sources, doublets, horse shoe vortices) and a constant porosity coefficient Q over the horizontal perforated walls is assumed. The coefficient Q was assessed from the comparison of aerodynamic coefficients of a reference model measured in the S2 perforated test section and in the S1MA very large wind tunnel (no wall effects).

Moreover, the effect of the model on the wind tunnel reference pressure tap is evaluated.

These corrections are usually calculated for ten Mach number values and at 2 incidence values by Mach number. They comprise two terms, one constant and the other proportional to the lift coefficient.

The wall effect is the effect of the infinite series of the “images” of each singularity induced by the four test section walls.

The sting effect is the direct effect of the singularities describing the sting and only corrections DM and $D\alpha$ at the wing are assessed.

- CFD RANS computation:

The sting effect can preferably be calculated by CFD RANS computations. Calculations with and without sting are performed and the sting effect is extracted. Corrections of aerodynamic coefficients on the entire model are assessed.

The extra cost for CFD RANS computation is 53k€ for 2 model configurations.

Base pressure correction

The base pressure correction results from the presence of a pressure coefficient different of zero inside the rear fuselage which is “open” to enable the sting entry. It consists in replacing, on the surface SK , the mean measured cavity pressure PK by the reference pressure $P0C$. Corrections on drag coefficient, lift coefficient and moment coefficient are calculated.
